

Catch Phish Email Analysis Tool

Educating and protecting users where they're most vulnerable - *their inbox.*

What is Catch Phish?

Catch Phish is an email analysis tool designed to educate users on how to positively identify phishing emails with the click of a button. Cyber criminals continue to choose phishing as their attack vector of choice, making a robust phishing program a critical component of every cybersecurity program. Catch Phish brings real-life education and real-time protection where users are most vulnerable - their inbox.

Catch Phish is available to all clients with access to the Employee Vulnerability Assessment (EVA), view service feature comparison here for eligible per-client subscriptions. Available as an Outlook add-in, Catch Phish makes training frictionless and increases productivity for users and the techs that receive the inevitable "Is this a phishing email?" inquiry! Powered by machine learning and artificial intelligence, Catch Phish is a sophisticated tool that continues to advance as cybercriminals alter and improve their tactics.

How does it work?

Breach Secure Now partners can offer routine simulated phishing tests to teach users how to identify malicious phishing attempts. If a user believes they've received a phishing email, they simply have to click "Catch Phish" in their toolbar! If a phishing simulation is correctly identified, users instantly earn a reward. When a user identifies an email not recognized as part of a phishing test, they are encouraged to confirm the validity with "Send for Analysis", a feature built to provide in-depth training by highlighting red flags found within the email so they can learn what to watch out for in future attempts.

What is analyzed during the Send for Analysis?

When a suspicious email has been identified that is not a recognized simulation and the employee clicks "Send for Analysis", our system instantly begins scanning the email looking for red flags under the following components:

Threatening Language

From flagged phrases to common words found in legitimate phishing emails, Catch Phish teaches users what language should raise a red flag!

Deep Link Analysis

Not only does Catch Phish analyze the links inside each email for malicious content, but it also identifies and scores all links present on the URL's destination page.

Attachment Scanning

While spam filters can usually identify malicious attachments, threats can still get through. Catch Phish analyzes every attachment for malicious content.

Key Phishing Identifiers

Catch Phish can identify hidden inconsistencies in emails, like different sender and recipient countries, that may aid users in identifying more sophisticated phishing tactics.
